**Abstract.** This exercise is constructed for BA students in Business Administration/International Management to practice the application of empirical methods such as a regression analysis in testing finance theories such as the behavior finance theory. In particular, the exercise tests for the existence of herd behavior by applying the regression model of Chang et al. (2000) in the case of the Swiss stock market in the global financial crisis period January 2007 – June 2010 as well as recently between January 2016 – June 2019. Publicly available daily stock price data and the Stata software were used.

## **1. Teaching Notes**

### **1.1. What are the learning objectives addressed by the teaching material?**

The learning objective is to apply an empirical method (already studied in the *Econometrics* course taught in the BA Business Administration/International Management Program) to test the herding concept within the behavior finance theory studied in Corporate Finance.

### **1.2. Which target group is this teaching material aimed at (e.g. BA/MA/FE)?**

The target group are BA students in Business Administration/International Management that have already completed the *Econometrics* and *Corporate Finance* classes.

### **1.3. What teaching methods were used with this material?**

An exercise is conducted by testing a herding behavior model by applying a regressional analysis.

### **1.4. How often was it used?**

It was taught in the Spring 2019 semester in the Context Course “*Financial Markets and Trends*” in the BA Business Administration/ International Management Program at the FHNW.

### **1.5. What was the experience of using it (self and external evaluation)?**

It was considered as a most useful exercise by students intending to write a BA Thesis based on an empirical analysis in the area of finance.

The success of the exercise pre-requires a good knowledge of regressional analysis and the Stata software.

### **1.6. Should special attention be given to particular aspects when using the teaching material?**

Availability of the software program Stata.

# **Exercise:**

## **Testing for Herd Behavior in the Swiss Stock Market**

**Abstract.** This exercise is constructed for BA students in Business Administration/International Management to practice the application of empirical methods such as a regression analysis in testing finance theories such as the behavior finance theory. In particular, the exercise tests for the existence of herd behavior by applying the regression model of Chang et al. (2000) in the case of the Swiss stock market in the global financial crisis period January 2007 – June 2010 as well as recently between January 2016 – June 2019. Publicly available daily stock price data and the Stata software were used.

## **2. The Exercise Task “Testing for Herd Behavior”**

Apply the model of Chang et al. (2000) explained in the Methodology part to test the existence of herd behavior in the Swiss Stock Market. Use the daily closing prices for the 19 large-caps in the Swiss Market Index 20 (SMI 20) and the SMI 20 values in the two time periods January 2007 – June 2010 and January 2016 – June 2019 in Attachment A and described in the Data part. Use Stata's *OLS estimator* from your econometrics classes. Interpret the results as per the guidelines in the Methodology part.

## **3. Introduction to the Herd Behavior Concept**

The concept of herd behavior belongs to the behavior finance theory promoted by academic works like the one of Thaler (2005). Herding “occurs when groups of investors emulate other successful investors and chase asset classes that are doing well” (Ehrhardt & Brigham, 2017).

Herd behavior of investors is generally considered to be irrational investor behavior. In case of herding, investors do not make their investment decisions based on existing models or empirical evidence but rather mimic the actions of the crowd. However, some studies have shown that irrational herding behavior is rather characteristic of individual investors, while institutional herding is rational and information-based (Lin et al., 2013). Furthermore, herding has been particularly observed in periods of market extreme fluctuations (Christie and Huang, 1995).

## **4. Empirical Analysis/Tests of Herd Behavior**

The herd behavior is studied by conducting empirical studies exploring the relationship between individual investor behavior characteristics and the overall market behavior. For example, Christie and Huang (1995) tested herding by using cross sectional standard deviation (CSSD) as a measure of average proximity of individual asset returns to the realized market average assuming a linear relationship between the two variables. They found evidence of herding behavior in periods of market extreme fluctuations.

Other empirical testing models include Lin et al. (2013), Olsen (1996), Lao and Singh (2011), Hwang und Salmon (2001), Froot et al. (1992).

Chang et al. (2000) extended the work of Christie and Huang and established a non-linear relationship between the level of equity return dispersions and the overall market return. Cross-sectional absolute deviations (CSAD) were taken as a measure for dispersion. The authors examined the presence of herding in both developing and developed countries. They found that herding was not present in developed economies but rather present in emerging economies.

The rationale of the Chang (2000) model is that when investors herd, they tend to follow the market trend and thus the return dispersion decreases or increases at a lower rate. Chang et al. (2000) suggested the cross sectional absolute deviation (CSAD) as the measure of return dispersion in the market to test for herd behavior.

Additional studies that have applied the Chang (2000) model include Malik and Elahi (2014), Ramadan (2015), and Caparrelli et al. (2004).

## 5. Methodology on Testing for Herd Behavior

Cross sectional absolute deviation (CSAD) is constructed as the measure of return dispersion between individual stock returns and the market returns (see Equation (1)).

CSAD is then regressed on the market returns and the square of the market returns (see Equation (2)).

The intuition behind the non-linear regressional model of Chang et al. (2000) is that “if market participants tend to follow aggregate market behavior and ignore their own priors during periods of large average price movements, then the linear and increasing relation between dispersion and market return will no longer hold” (p. 1655).

A statistically significant negative value of the coefficient  $y_2$  in Equation (2) would indicate the presence of herd behavior. The authors clarify that “if during periods of relatively large price swings, market participants do indeed herd around indicators such as the average consensus of all market constituents, a non-linear relation between CSAD and the average market return would result. The non-linearity would be captured by a negative and statistically significant  $y_2$  coefficient” (Chang et al., 2000, p. 1657).

The basic equations for the calculation of the CSAD (1) and the herding regression (2) are:

$$CSAD_t = \frac{1}{N} \sum_{i=1}^N |R_{i,t} - R_{m,t}| \quad (1)$$

$$CSAD_t = y_0 + y_1 |R_{m,t}| + y_2 R_{m,t}^2 + \varepsilon_t \quad (2)$$

$R_{i,t}$  denotes the individual stock return at time t and  $R_{m,t}$  the return of the market at time t.

$R_{i,t}$  and  $R_{m,t}$  are calculated as simple returns where  $R_{i,t} = 100 * (P_{i,t} / P_{i,t-1})$  and  $R_{m,t} = 100 * (P_{m,t} / P_{m,t-1})$ .

## 6. Data

The data used for the analysis contains the daily closing prices of the 19 large-caps included in the Swiss Market Index 20 (SMI 20) and the closing values of the index over two time periods capturing the global financial crisis period between January 2007 and June 2010 as well as the last years of January 2016 to June 2019. The SMI 20 is considered an appropriate benchmark since the introduction of capped weighting in 2017 to address the fact that the top three constituents (Nestlé, Roche, Novartis) account for more than 60% of the index capitalization. Currently, the weight of any constituent in the SMI index cannot exceed 18%.

The publicly available data was retrieved from the website [www.finanzen.ch](http://www.finanzen.ch) and is provided in Attachment A.

Missing dates are due to the fact of closed stock exchanges on the weekend and official holidays.

## 7. Results and Interpretation

Figure 1 and 2 below present the results of the OLS regression ran with Stata on the two time periods.

Source	SS	df	MS	Number of obs	=	16,465

Figure 2: Results on OLS regression from Stata for the time period January 2016 – June 2019

In both studied time periods, 2007 - 2010 and 2016 - 2019 the coefficient estimates in front of the variable of interest  $R_m^2$  is positive and close to zero (see Fig. 1 and Fig.2). Therefore, it could be concluded, that in both time periods there is no evidence of herding behavior. This evidence supports the findings of Chang et al. (2000) that in developed countries like Switzerland, herding could not be proven. However, the coefficient estimate in front of  $R_m^2$  in the period 2016 – 2019 is slightly larger than the one in the period 2007 – 2010. This could imply that, even though there is no clear evidence of herding behavior in both periods, the tendency towards herding behavior is stronger in phases of distressed markets, such as during the global financial crisis in 2007-2008 and shortly afterwards.

However, the p-value of the estimated coefficient in front of  $R_m^2$  in the first time period is 0.479, and thus larger than 0.05 (see Fig. 1). Therefore, the hypothesis that the coefficient in front of  $R_m^2$  is different from 0, cannot be rejected, and thus the result is not statistically significant. The corresponding t-value of  $R_m^2$  for the first time period is 0.71, which is below the minimum required value of 1.96 based on the 95% confidence interval, confirming the statistical insignificance of  $R_m^2$  in the first time period. Since,

however, this is the only limitation in the regression results for the first time period, and the absolute market return variable (*absrm*) is statistically significant, the results can still be used for the overall analysis. The coefficient in front of  $R_m^2$  in the second time period 2016 – 2019 has a p-value of 0.029 and thus is statistically significant see Fig. 2).

Both R-squared values of 0.0040 for time period one and 0.0154 for period two are rather low, which means that a large part of the variance in the predicted variable *CSAD* could not be explained by the two variables *absrm* and  $R_m^2$  (see Fig. 1 and Fig. 2). This limitation points towards the existence of further influential factors that are not covered by the chosen model. Still the higher R-squared for the second period as well as the statistically significant coefficient  $y_2$  from the second regression indicate that the chosen model has a stronger explanatory power for the second time period 2016 – 2019 as compared to the regressive results for the first period 2007 – 2010.
